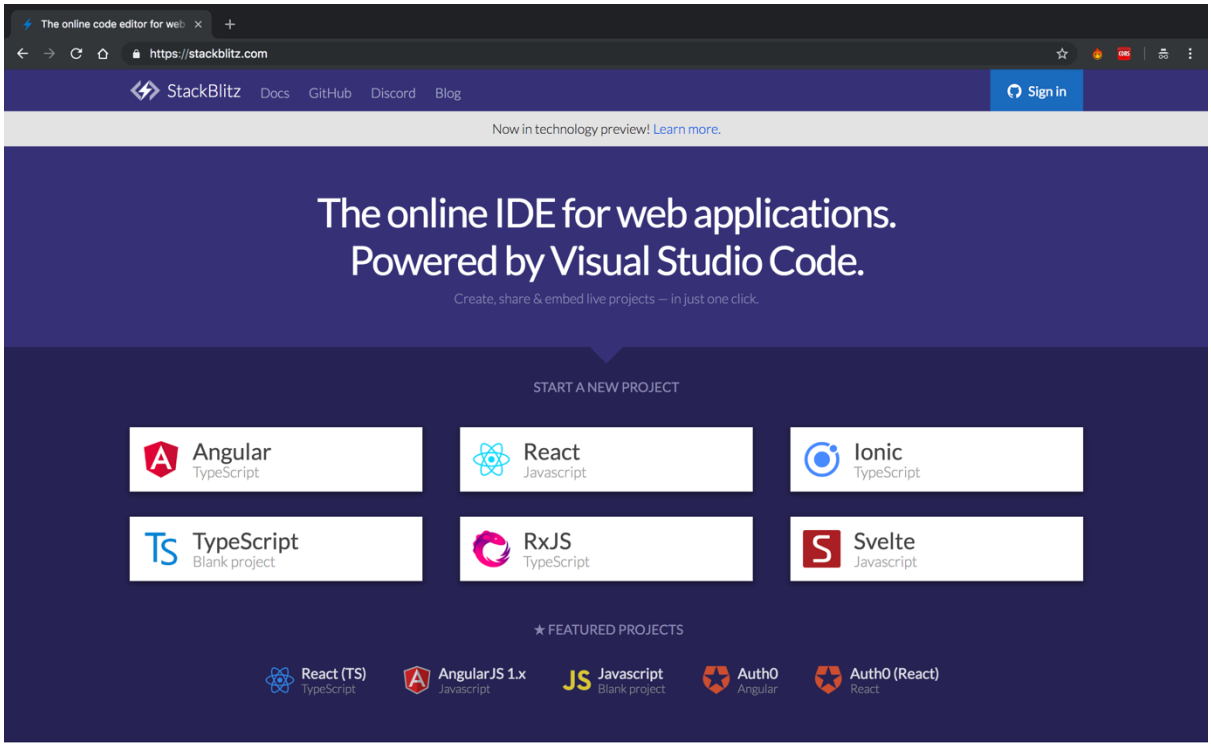
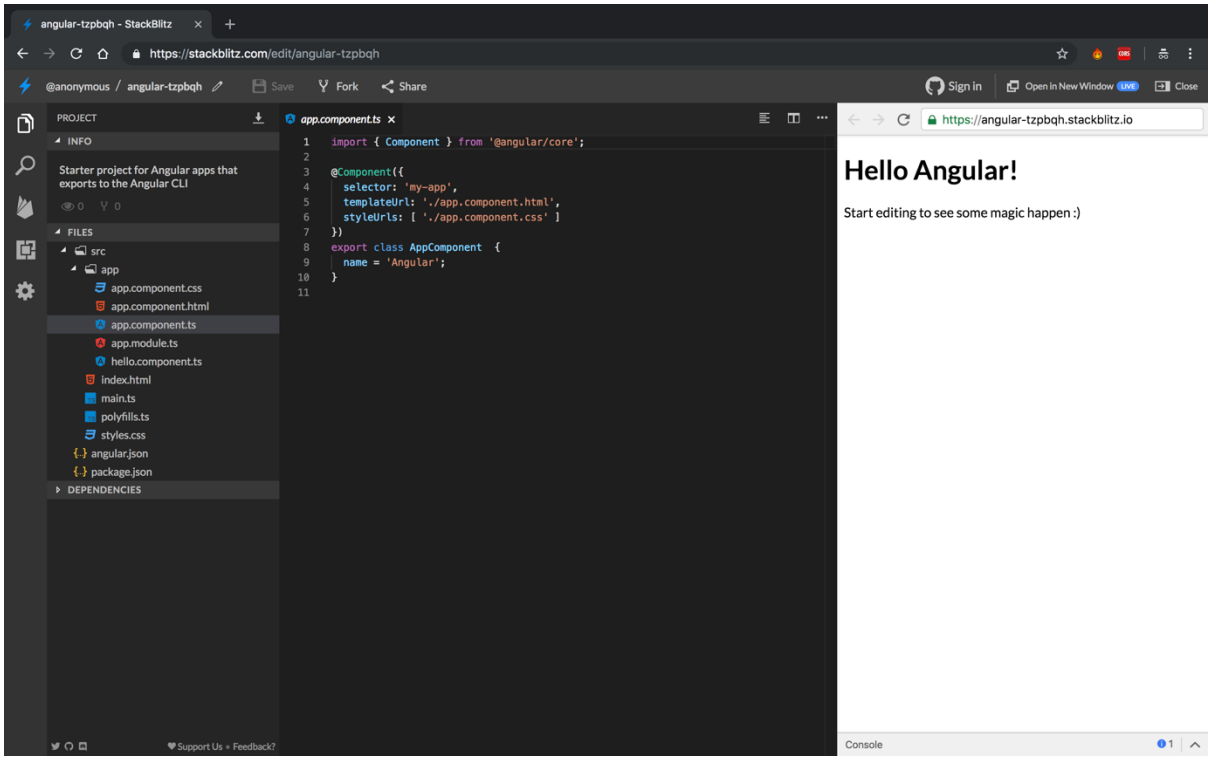
To perform your code-exercises, you will have to create separate projects. Doing this for each code-exercise can be very tiresome and tedious. Therefore, you have the option of using StackBlitz instead of creating the project on your computer. However, you are free to make a choice and create a project on your computer if you want.

Here is a handy guide that will help you get started with StackBlitz and setup an Angular project with Bootstrap. Feel free to skip this guide if you do not want to use StackBlitz.

Head over to stackblitz.io. You will land on the homepage of StackBlitz application.



You can login using your GitHub account or you can keep working as a guest. Click on the Angular button to start a new Angular project. A new project will be created in a few seconds and you will be taken to your first Angular project on StackBlitz.



As you can see, the screen is divided into 3 different panes.

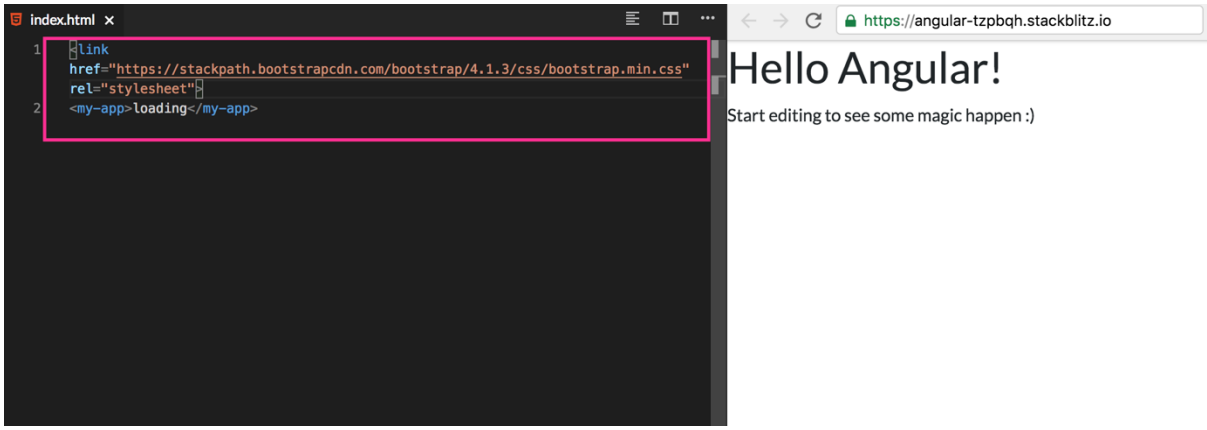
1. The first pane, on the left is the File Explorer just as you have in VS Code.
2. The middle pane is the code editor that displays the selected file and allows you to edit and save the changes.
3. The last pane, the one of the right, is the output. It shows you your application and refreshes automatically when the code is changes and saved in the middle pane.

You will find a very familiar structure in this project. Most things are exactly like we have in a project created using Angular CLI on our computer.

Next is bringing in Bootstrap to apply the styles. Since all the code in the project uses Bootstrap, this is required if you want your project to look good. To bring in bootstrap, add the following code to the top in your index.html file and save the changes.

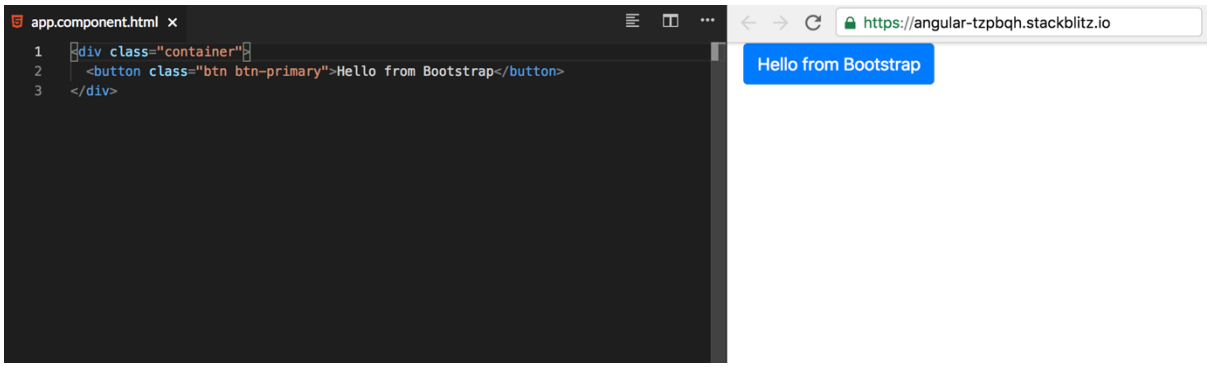
```
<link
href="https://stackpath.bootstrapcdn.com/bootstrap/4.1.3/css/bootstrap.min.css"
rel="stylesheet">
```

As you save the index.html file, the output window will refresh the browser and you will see the text styles change.

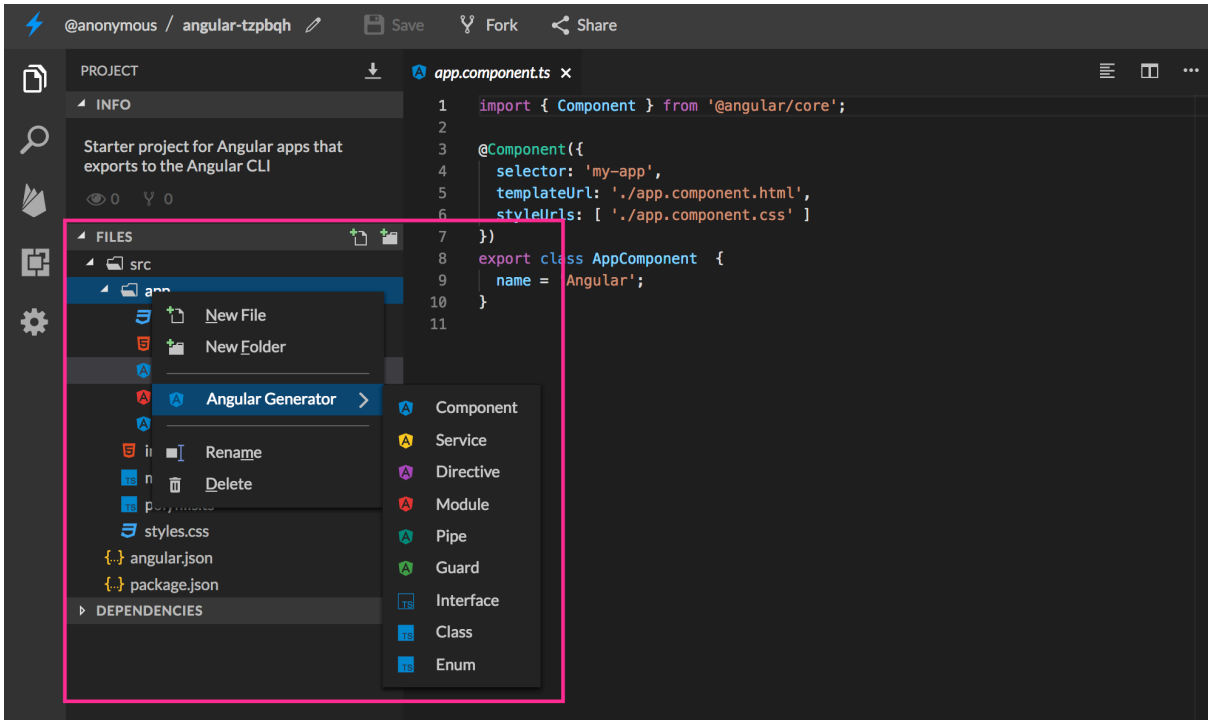


That's because Bootstrap is applied successfully.

Now, you can easily use all the bootstrap classes for buttons, containers, margin etc.



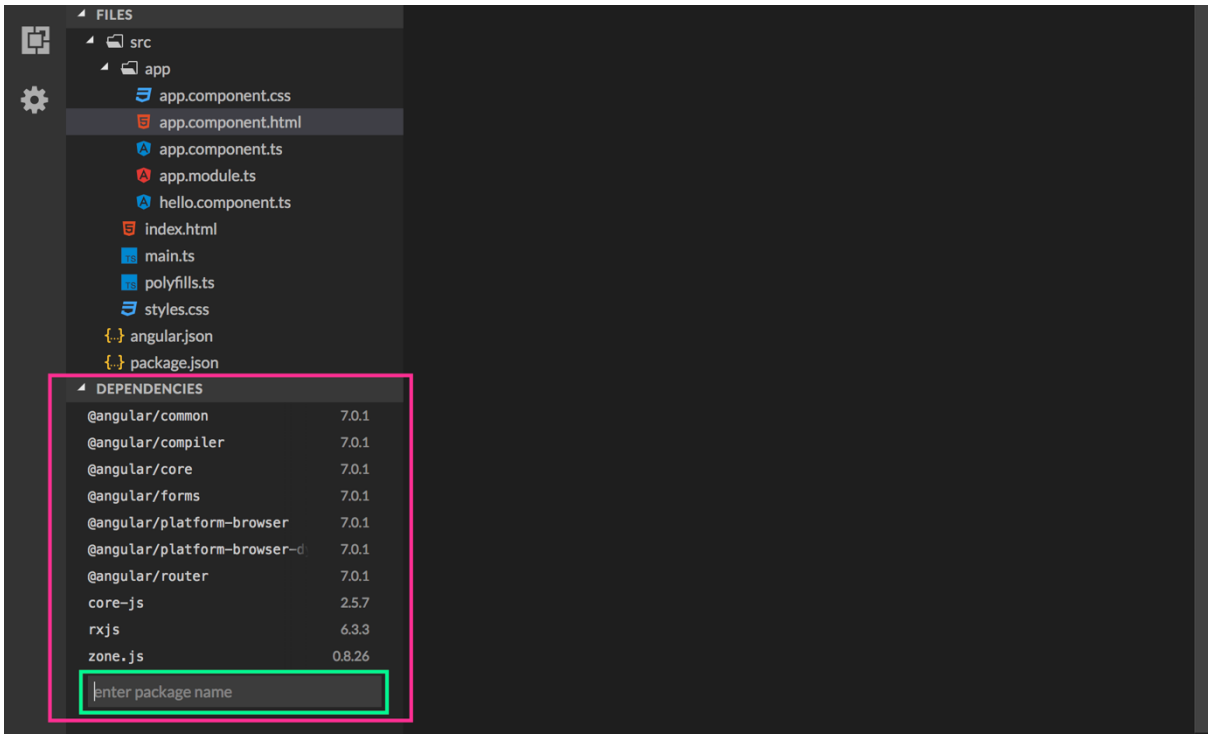
Keep in mind that you cannot run CLI commands on Stackblitz to create components and other things. To create new components, services or even pipes, you can use the generator. To use the generate, click on the folder (inside which you want to create a component , service or pipe) and select Angular Generator.



This will give you a list of new things you can create, from Component, Services and Pipes, to everything you will ever need. Select anyone, and it will be created.

You can however, create them manually, if you like to do that.

To install any Node Modules, for example firebase, you can use the Dependencies section.



Add the name of the new module/package in the textbox at the bottom (for example "***firebase***" and press Enter. The new module will be installed in no time and will be available for you to import in all your files.

Finally, when you are done, you can share the public URL of the project with the instructor and your teachers and friends to let them view your application without showing them the code.

A little secret, this is how we created all the Code Exercises and Assignments for you. All the best.
